Task#05 - JUnit Testing

Implement a method named **verify_email_address( )**. This method should be used to verify an email address to check if it is a valid email address or not e.g. if a person enters abc123.com as an email address then it should be considered an invalid email address. A message should be shown to the user to inform him about the error.
Use the following rules to validate the email address:

1. Alphabets, numbers allowed before @, the only two special characters allowed are . (full stop) and – (minus/dash).
2. Only gmail.com, hotmail.com, live.com and yahoo.com allowed after @.

Consider yourself as a tester, write unit tests to check whether the verify_email_address( ) method works properly. If the verify_email_address( ) allows an invalid email address the test should fail, it should pass otherwise.
